## 1 Introduction

The package "NormqPCR" provides methods for the normalization of real-time quantitative RT-PCR data. In this vignette we describe and demonstrate the available functions. Firstly we show how the user may combine technical replicates, deal with undetermined values and deal with values above a user-chosen threshold. The rest of the vignette is split into two distinct sections, the first giving details of different methods to select the best houskeeping gene/genes for normalisation, and the second showing how to use the selected housekeeping gene(s) to produce  $2^{-\Delta Cq}$  normalised estimators and  $2^{-\Delta\Delta Cq}$  estimators of differential expression.

# 2 Combining technical replicates

When a raw data file read in using read.qPCR contains technical replicates, they are dealt with by concatenating the suffix \_TechRep.n to the detector name, where n in 1, 2...N is the number of the replication in the total number of replicates, N, based on order of appearence in the qPCR data file.

So if we read in a file with technical replicates, we can see that the detector/feature names are thus suffixed:

```
> library(ReadqPCR) # load the ReadqPCR library
> library(NormqPCR)
> path <- system.file("exData", package = "NormqPCR")
> qPCR.example.techReps <- file.path(path, "qPCR.techReps.txt")
> qPCRBatch.qPCR.techReps <- read.qPCR(qPCR.example.techReps)
> rownames(exprs(qPCRBatch.qPCR.techReps))[1:8]

[1] "gene_aj_TechReps.1" "gene_aj_TechReps.2" "gene_al_TechReps.1"
[4] "gene_al_TechReps.2" "gene_ax_TechReps.1" "gene_ax_TechReps.2"
[7] "gene_bo_TechReps.1" "gene_bo_TechReps.2"
```

It is likely that before continuing with the analysis, the user would wish to average the technical replicates by using the arithmetic mean of the raw Cq values. This can be achieved using the combineTechReps function, which will produce a new qPCRBatch object, with all tech reps reduced to one reading:

```
> combinedTechReps <- combineTechReps(qPCRBatch.qPCR.techReps)
> combinedTechReps

qPCRBatch (storageMode: lockedEnvironment)
assayData: 8 features, 3 samples
   element names: exprs
protocolData: none
phenoData
   sampleNames: one three two
   varLabels: sample
   varMetadata: labelDescription
featureData: none
experimentData: use 'experimentData(object)'
Annotation:
```

# 3 Dealing with undetermined values

When an RT-qPCR experiment does not produce a reading after a certain number of cycles (the cycle threshold), the reading is given as undetermined. These are represented in qPCRBatch objects as NA. Different users may have different ideas about how many cycles they wish to allow before declaring a detector as not present in the sample. There are two methods for the user to decide what to do with numbers above a given cycle threshold:

First the user might decide that anything above 38 cycles means there is nothing present in their sample, instead of the standard 40 used by the taqman software. They can replace the value of all readings above 38 as NA using the following:

Firstly read in the taqman example file which has 96 detectors, with 4 replicates for mia (case) and 4 non-mia (control):

```
> path <- system.file("exData", package = "NormqPCR")
> taqman.example <- file.path(path, "/example.txt")
> qPCRBatch.taqman <- read.taqman(taqman.example)</pre>
```

We can see that for the detector: Ccl20.Rn00570287\_m1 we have these readings for the different samples:

> exprs(qPCRBatch.taqman)["Ccl20.Rn00570287\_m1",]

fp.4.day.3.v fp.7.day.3.mia fp.8.day.3.mia

NA

```
fp1.day3.v fp2.day3.v fp5.day3.mia fp6.day3.mia fp.3.day.3.v NA NA 35.74190 34.05922 35.02052 fp.4.day.3.v fp.7.day.3.mia fp.8.day.3.mia NA 35.93689 36.57921
```

We can now use the replaceAboveCutOff method in order to replace anything above 35 with NA:

It may also be the case that the user wants to get rid of all NA values, and replace them with an arbitrary number. This can be done using the replaceNAs method. So if the user wanted to replace all NAs with 40, it can be done as follows:

```
> qPCRBatch.taqman.replaced <- replaceNAs(qPCRBatch.taqman, newNA = 40)
> exprs(qPCRBatch.taqman.replaced)["Cc120.Rn00570287_m1",]
```

In addition, the situation sometimes arises where some readings for a given detector are above a given cycle threshold, but some others are not. The user may decide for example that if a given number of readings are NAs, then all of the readings for this detector should be NAs. This is important because otherwise an unusual reading for one detector might lead to an inaccurate estimate for the expression of a given gene.

This process will necessarily be separate for the different sample types, since you might expect a given gene to show expression in one sample type compared to another. Therefore it is necessary to designate the replicates per sample type using a contrast matrix. It is also necessary to make a sampleMaxMatrix which gives a maximum number of NAs allowed for each sample type.

So in the example file above we two sample types, with 4 biological replicates for each, the contrastMatrix and sampleMaxMatrix might be contructed like this:

#### > sampleNames(qPCRBatch.taqman)

```
[1] "fp1.day3.v" "fp2.day3.v" "fp5.day3.mia" "fp6.day3.mia"
[5] "fp.3.day.3.v" "fp.4.day.3.v" "fp.7.day.3.mia" "fp.8.day.3.mia"

> a <- c(0,0,1,1,0,0,1,1) # one for each sample type, with 1 representing

> b <- c(1,1,0,0,1,1,0,0) # position of sample type in samplenames vector

> contM <- cbind(a,b)

> colnames(contM) <- c("case", "control") # set the names of each sample type

> rownames(contM) <- sampleNames(qPCRBatch.taqman) # set row names

> contM
```

	case	control
fp1.day3.v	0	1
fp2.day3.v	0	1
fp5.day3.mia	1	0
fp6.day3.mia	1	0
fp.3.day.3.v	0	1
fp.4.day.3.v	0	1
<pre>fp.7.day.3.mia</pre>	1	0
fp.8.day.3.mia	1	0

More details on contrast matrices can be found in the limma manual, which requires a similar matrix when testing for differential expression between samples.

For example, if the user decides that if at least 3 out of 4 readings are NAs for a given detector, then all readings should be NA, they can do the following, using the makeAll-NewVal method:

Here you can see for the Ccl20.Rn00570287\_m1 detector, the control values have been made all NA, wheras before 3 were NA and one was 35. However the case values have been kept, since they were all below the NA threshold. It is important to filter the data in this way to ensure the correct calculations are made downstream when calculating variation and other parameters.

> exprs(qPCRBatch.tagman.replaced)["Cc120.Rn00570287\_m1",]

```
fp1.day3.v fp2.day3.v fp5.day3.mia fp6.day3.mia fp.3.day.3.v NA NA 35.74190 34.05922 NA fp.4.day.3.v fp.7.day.3.mia fp.8.day.3.mia NA 35.93689 36.57921
```

# 4 Selection of most stable reference/housekeeping genes

This section contains two subsections containing different methods for the selection of appropriate housekeeping genes.

#### 4.1 geNorm

We describe the selection of the best (most stable) reference/housekeeping genes using the method of Vandesompele et al  $(2002)^{\tilde{}}[3]$  (in the sequel: Vand02) which is called *geNorm*. We first load the package and the data

```
> options(width = 68)
> data(geNorm)
> str(exprs(geNorm.qPCRBatch))
```

```
num [1:10, 1:85] 0.0425 0.0576 0.1547 0.1096 0.118 ...
- attr(*, "dimnames")=List of 2
..$ : chr [1:10] "ACTB" "B2M" "GAPD" "HMBS" ...
..$ : chr [1:85] "BM1" "BM2" "BM3" "BM4" ...
```

We start by ranking the selected reference/housekeeping genes. The geNorm algorithm implemented in function selectHKs proceeds stepwise; confer Section "Materials and methods" in Vand02. That is, the gene stability measure M of all candidate genes is computed and the gene with the highest M value is excluded. Then, the gene stability measure M for the remaining gene is calculated and so on. This procedure is repeated until two respectively, minNrHK genes remain.

```
> tissue <- as.factor(c(rep("BM", 9), rep("FIB", 20), rep("LEU", 13),
                       rep("NB", 34), rep("POOL", 9)))
> res.BM <- selectHKs(geNorm.qPCRBatch[,tissue == "BM"], method = "geNorm",
                       Symbols = featureNames(geNorm.qPCRBatch),
+

```

#### Remark 1:

Since the computation is based on gene ratios, the two most stable control genes in each cell type cannot be ranked.

We plot the average expression stability M for each cell type (see Figure 2 in Vand02).

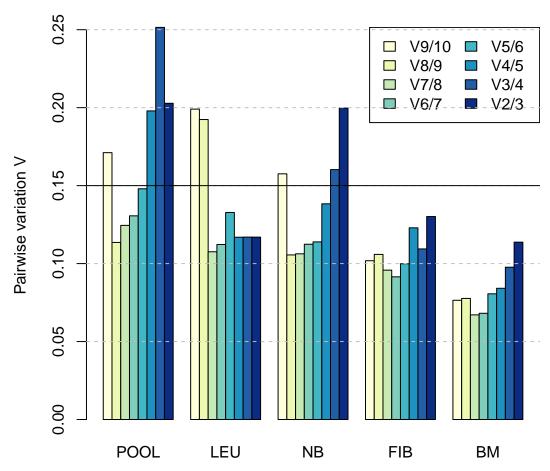

Second, we plot the pairwise variation for each cell type (see Figure 3 (a) in Vand02)

```
> legend("topright", legend = c("V9/10", "V8/9", "V7/8", "V6/7", "V5/6", "V4/5", "V3/4", "V2/3"),
+ fill = mypalette, ncol = 2)
> abline(h = seq(0.05, 0.25, by = 0.05), lty = 2, col = "grey")
> abline(h = 0.15, lty = 1, col = "black")
```

# Figure 3(a) in Vandesompele et al. (2002)

#### Remark 2:

Vand02 recommend a cut-off value of 0.15 for the pairwise variation. Below this bound the inclusion of an additional housekeeping gene is not required.

#### 4.2 NormFinder

The second method for selection reference/housekeeping genes implemented in package is the method derived by [1] (in the sequel: And04) called *NormFinder*. The ranking contained in Table~3 of And04 can be obtained via

```

As we are often interested in more than one reference/housekeeping gene we also implemented a step-wise procedure of the NormFinder algorithm explained in Section "Average control gene" in the supplementary information of And04. This procedure is available via function selectHKs.

```
> Class <- pData(Colon)[,"Classification"]</pre>
> selectHKs(Colon, group = Class, log = FALSE, trace = TRUE,
            Symbols = featureNames(Colon), minNrHKs = 12,
            method = "NormFinder")$ranking

# 5 Normalization by means of reference/housekeeping genes

## 5.1 $\Delta Cq$ method using a single housekeeper

The  $\Delta Cq$  method normalises detectors within a sample by subtracting the cycle time value of the housekeeper gene from the other genes. This can be done in NormqPCR as follows: for the example dataset from "ReadqPCR" we must first read in the data:

```
> path <- system.file("exData", package = "NormqPCR")
> taqman.example <- file.path(path, "example.txt")
> qPCR.example <- file.path(path, "qPCR.example.txt")
> qPCRBatch.taqman <- read.taqman(taqman.example)</pre>
```

We then need to supply a housekeeper gene to be subtracted:

```
> qPCRBatch.norm <- deltaCq(qPCRBatch = qPCRBatch.taqman, hkgs = hkgs, calc="arith")
> head(exprs(qPCRBatch.norm))

This returns a new qPCRBatch, with new values in the exprs slot. This will be compatible with many other bioconductor and R packages, such as heatmap.

Note these numbers might be negative. For further analysis requiring postive values only, 2° can be used to transform the data into  $2^{\Delta CT}$  values.

#### 5.2 $\Delta Cq$ method using a combination of housekeeping genes

If the user wishes to normalise by more than one housekeeping gene, for example if they have found a more than one housekeeping gene using the NormFinder/geNorm algorithms described above, they can. This is implemented by calculating the average of these values to form a "pseudo-housekeeper" which is subtracted from the other values. So using the same dataset as above, using housekeeping genes GAPDH, Beta-2-microglobulin and Beta-actin, the following steps would be taken:

```
> hkgs<-c("Actb-Rn00667869_m1", "B2m-Rn00560865_m1", "Gapdh-Rn99999916_s1")
> qPCRBatch.norm <- deltaCq(qPCRBatch = qPCRBatch.taqman, hkgs = hkgs, calc="arith")
> head(exprs(qPCRBatch.norm))
```

```

# 5.3 $2^{-\Delta\Delta Cq}$ method using a single housekeeper

It is possible to use the  $2^{-\Delta\Delta Cq}$  method for calculating relative gene expression between two sample types. Both the same well and the separate well methods as detailed in [2] can be used for this purpose, and will produce the same answers, but with different levels of variation. By default detectors in the same sample will be paired with the housekeeper, and the standard deviation used will be that of the differences between detectors and the housekeepers. However, if the argument paired=FALSE is added, standard deviation between case and control will be calculated as  $s = \sqrt{s_1^2 + s_2^2}$ , where  $s_1$  is the standard deviation for the detector readings and  $s_2$  is the standard deviation the housekeeper gene readings. The latter approach is not recommended when the housekeeper and genes to be compared are from the same sample, as is the case when using the taqman cards, but is included for completeness and for situations where readings for the housekeeper might be taken from a separate biological replicate (for example in a post hoc manner due to the originally designated housekeeping genes not performing well), or for when NormqPCR is used for more traditional qPCR where the products undergo amplifications from separate wells.

for the example dataset from "ReadqPCR" we must first read in the data:

```
> path <- system.file("exData", package = "NormqPCR")
```

```
> taqman.example <- file.path(path, "example.txt")
> qPCR.example <- file.path(path, "qPCR.example.txt")
> qPCRBatch.taqman <- read.taqman(taqman.example)</pre>
```

deltaDeltaCq also requires a contrast matrix. This is to contain columns which will be used to specify the samples representing case and control which are to be compared, in a similar way to the "limma" package. these columns should contain 1s or 0s which refer to the samples in either category:

```
> contM <- cbind(c(0,0,1,1,0,0,1,1),c(1,1,0,0,1,1,0,0))
> colnames(contM) <- c("interestingPhenotype","wildTypePhenotype")
> rownames(contM) <- sampleNames(qPCRBatch.taqman)
> contM
```

#### interestingPhenotype wildTypePhenotype

fp1.day3.v	0	1
fp2.day3.v	0	1
fp5.day3.mia	1	0
fp6.day3.mia	1	0
fp.3.day.3.v	0	1
fp.4.day.3.v	0	1
fp.7.day.3.mia	1	0
fp.8.day.3.mia	1	0

We can now normalise each sample by a given housekeeping gene and then look at the ratio of expression between the case and control samples. Results show (by column): 1) Name of gene represented by detector. 2) Case  $\Delta Cq$  for the detector: the average cycle time for this detector in the samples denoted as "case" - the housekeeper cycle time. 3) the standard deviation for the cycle times used to calculate the value in column 2). 4) Control  $\Delta Cq$  for the detector: the average cycle time for this detector in the samples denoted as "controller", or the "callibrator" samples - the housekeeper cycle time. 5) The standard deviation for the cycle times used to calculate the value in column 4). 6)  $2^{-\Delta \Delta Cq}$  - The difference between the  $\Delta Cq$  values for case and control. We then find  $2^-$  of this value. 7) and 8) correspond to 1 s.d. either side of the mean value, as detailed in [2].

                                                                     NA
6
             7.668e-02 0.413128242070071
                                                        NA
                                                                     NA
```

We can also average the taqman data using the separate samples/wells method. Here standard deviation is calculated separately and then combined, as described above. Therefore the pairing of housekeeper with the detector value within the same sample is lost. This can potentially increase variance.

```

# 5.4 $2^{\Delta\Delta Cq}$ method using a combination of housekeeping genes

If the user wishes to normalise by more than one housekeeping gene, for example if they have found a more than one housekeeping gene using the NormFinder/geNorm algorithms described above, they can. This is implemented by calculating the average of these values using the geometric mean to form a "pseudo-housekeeper" which is subtracted from the other values. For the dataset above, using housekeeping genes GAPDH, Beta-2-microglobulin and Beta-actin:

```
> qPCRBatch.taqman <- read.taqman(taqman.example)
> contM <- cbind(c(0,0,1,1,0,0,1,1),c(1,1,0,0,1,1,0,0))
> colnames(contM) <- c("interestingPhenotype", "wildTypePhenotype")
> rownames(contM) <- sampleNames(qPCRBatch.taqman)
> hkgs<-c("Actb-Rn00667869_m1", "B2m-Rn00560865_m1", "Gapdh-Rn99999916_s1")</pre>
> ddCq.gM.taqman <- deltaDeltaCq(qPCRBatch = qPCRBatch.taqman, maxNACase=1, maxNAControl=1,
+
                                  hkgs=hkgs, contrastM=contM, case="interestingPhenotype",

## TO SHOW EXAMPLE USING GENORM/NORMFINDER DATA

### 5.5 Compute NRQs

#### THIS FUNCTION IS STILL EXPERIMENTAL!

We load a dataset including technical replicates.

```
> path <- system.file("exData", package = "ReadqPCR")
> qPCR.example <- file.path(path, "qPCR.example.txt")</pre>
```

> Cq.data <- read.qPCR(qPCR.example)</pre>

We combine the technical replicates and in addition compute standard deviations.

```
> Cq.data1 <- combineTechRepsWithSD(Cq.data)</pre>
```

We load efficiencies for the dataset and add them to the dataset.

```
> Effs <- file.path(path, "Efficiencies.txt")
> Cq.effs <- read.table(file = Effs, row.names = 1, header = TRUE)
> rownames(Cq.effs) <- featureNames(Cq.data1)
> effs(Cq.data1) <- as.matrix(Cq.effs[,"efficiency",drop = FALSE])
> se.effs(Cq.data1) <- as.matrix(Cq.effs[,"SD.efficiency",drop = FALSE])</pre>
```

Now we can compute normalized relative quantities for the dataset where we consider two of the included features as reference/housekeeping genes.

```
> res <- ComputeNRQs(Cq.data1, hkgs = c("gene_az", "gene_gx"))
> ## NRQs
> exprs(res)
```
